Aspirin and Cardiovascular Risk: A Clinical Study

Aspirin reduces cardiovascular risk in patients with a history of heart disease. This finding was reported by Smith et al. in a large clinical trial. The study included over 10,000 participants. Researchers observed a significant reduction in cardio-vascular events among the treatment group.

Contradicting Evidence Section

A separate cohort study found that Drug A has no effect on recovery time. This contradicts earlier reports of a positive effect. Further randomized controlled trials are needed to resolve this disagreement.
